# Script SleepMode.cmd

Description

The *SleepMode.cmd* script deactivates the standby and hibernate mode by changing the system registry's corresponding power settings, if necessary. Notice that this kind of deactivation also disables the start menu's options to manually switch to any power saving mode.

Usage

Right-click the *SleepMode.cmd* script to run it with administrative privileges. Afterwards restart Windows.

Note

The changed power setting takes effect after a restart.
